# Type Systems as Macros

Stephen Chang Alex Knauth Ben Greenman

PLT @ Northeastern University {stchang,alexknauth,types}@ccs.neu.edu

#### **Abstract**

We present TURNSTILE, a metalanguage for creating typed embedded languages. To implement the type system, programmers write type checking rules resembling traditional judgment syntax. To implement the semantics, they incorporate elaborations into these rules. TURNSTILE critically depends on the idea of linguistic reuse. It exploits a *macro system* in a novel way to *simultaneously* type check and rewrite a surface program into a target language. Reusing a macro system also yields modular implementations whose rules may be mixed and matched to create other systems. Combined with compiler and runtime reuse, TURNSTILE produces performant typed languages with little effort.

# 1. Typed Embedded Languages

As Paul Hudak asserted, "we really don't want to build a programming language from scratch ... better, let's inherit the infrastructure of some other language" [24]. Unsurprisingly, many modern languages support the creation of such embedded languages [4, 19, 21, 22, 25, 26, 28, 39, 41, 44].

Programmers who wish to create *typed* embedded languages, however, have more limited options. Such languages typically reuse their host's type system but, as a prominent project [43] recently remarked, this "*confines* them to (that) type system." Also, reusing a type system may not create proper abstractions, e.g., type errors may be reported in host language terms. At the other extreme, a programmer can implement a type system from scratch [40], expending considerable effort and passing up many of the reuse benefits that embedding a language promises in the first place.

We present an alternative approach to implementing typed embedded languages. Rather than reuse a type system, we embed a type system in a host's *macro system*. In other words, type checking is computed as part of macro expansion. Such an embedding fits naturally since a typical

type checking algorithm traverses a surface program, synthesizes information from it, and uses this information to rewrite the program, if it satisfies certain conditions, into a target language. This kind of algorithm exactly matches the ideal use case for macros. From this perspective, a type checker resembles a special instance of a macro system and our approach exploits synergies resulting from this insight.

With our macro-based approach, programmers may implement arbitrary type rules, yet they need not create a type system from scratch as they may reuse many parts of a macro system for type checking. Indeed, programmers need only supply their desired type rules in an intuitive mathematical form. Creating type systems with macros also fosters robust linguistic abstractions, e.g., they report type errors with surface language terms. Finally, our approach produces naturally modular type systems that dually serve as libraries of mixable and matchable type rules, enabling further reuse. When combined with the standard compiler, runtime, and tools reuse that embedded languages enjoy, our approach inherits the performance of its host and thus produces practical typed languages with little effort.

We use Racket [13, 16], a Lisp and Scheme descendant, as our host language since Lisps are already a popular platform for creating embedded languages [18, 21]. Racket's macro system in particular continues to evolve its predecessors [15] and has even influenced macro system design in modern non-Lisp languages [7, 9, 11, 46]. Thus programmers have created Racket-embedded languages for accomplishing a variety of tasks such as book publishing [8], program synthesis [42], and writing secure shell scripts [32].

The first part of the paper (§2-3) demonstrates a connection between type rules and macros by reusing Racket's macro infrastructure for type checking in the creation of a typed embedded language. The second part (§4) introduces TURNSTILE, a metalanguage that abstracts the insights and techniques from the first part into convenient linguistic constructs. The third part (§5-7) shows that our approach both accommodates a variety of type systems and scales to realistic combinations of type system features. We demonstrate the former by implementing fifteen core languages ranging from simply-typed to  $F_{\omega}$ , and the latter with the creation of a full-sized ML-like functional language that also supports Haskell-style type classes.

# 2. Creating Embedded Languages in Racket

This section summarizes the creation of embedded languages with Racket. Racket is not a single language but rather an ecosystem with which to create languages [13]. Racket code is organized into modules, e.g. LAM:<sup>1</sup>

A #lang racket declaration allows LAM to use forms and functions from the main Racket language. LAM defines and exports one macro, lm, denoting single-argument functions. A Racket macro<sup>2</sup> consumes and produces *syntax object* data structures. The lm macro specifies its usage with input pattern  $(lm \ x \ e)$  (in yellow to help readability<sup>3</sup>), which binds *pattern variables* x and e to subpieces of the input, the parameter and body, respectively. The output syntax  $(\lambda \ (x) \ e)$  (gray denotes syntax object construction) references these pattern variables  $(\lambda \ is \ Racket \ s \ \lambda)$ .

A module serves multiple roles in the Racket ecosystem. Running LAM as a *program* produces no result since it consists of only a macro definition. But LAM is also a *language*:

```
#lang lam  (\mbox{lm x (lm y x))} \quad ; => \langle \mbox{function} \rangle \\ ((\mbox{lm x x) (lm x x))} \quad ; \mbox{stx error! fn application undefined}
```

A module declaring #lang lam may only write lm functions; using any other form results in an error. A Racket module may also serve as a *library*, as in the following LC module:

```
#lang racket [LC]
(require lam) (provide (rename [lm \lambda][app #%app]))
(define-m (app e<sub>fn</sub> e<sub>arg</sub>) (#%app e<sub>fn</sub> e<sub>arg</sub>))
```

LC imports 1m from LAM and also defines app, which corresponds to single-argument function application. LC exports 1m and app with new names,  $\lambda$  and #%app, respectively. The #%app in the output of app is core-Racket's function application form, though programmers need not write it explicitly. Instead, macro expansion implicitly inserts it before applied functions. This enables modifying the behavior of function application, as we do here by exporting app as #%app. Thus a program in the LC language looks like:

where  $\lambda$  corresponds to 1m in LAM and applying a  $\lambda$  behaves according to app in LC. Running LC-PROG loops forever.

Figure 1 depicts compilation of a Racket program, which includes macro expansion. The Racket compiler first "reads" a program's surface text into a syntax object, which is a tree of symbols and literals along with context information, e.g.,

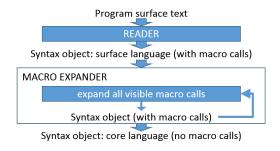

Figure 1. The Racket compiler's frontend

```
\begin{array}{lll} \tau = \tau \rightarrow \tau & e = x \mid \lambda x \colon \tau \cdot e \mid e \cdot e & \Gamma = x \colon \tau, \dots & \text{(types, terms)} \\ \frac{x \colon \tau \in \Gamma}{\Gamma \vdash x \colon \tau} & \text{($T$-VAR)} & \frac{\Gamma, x \colon \tau_1 \vdash e \colon \tau_2}{\Gamma \vdash \lambda x \colon \tau_1 \cdot e \colon \tau_1 \rightarrow \tau_2} & \text{($T$-ABS)} \\ & \frac{\Gamma \vdash e_1 \ \colon \tau_1 \rightarrow \tau_2 & \Gamma \vdash e_2 \ \colon \tau_1}{\Gamma \vdash e_1 \cdot e_2 \ \colon \tau_2} & \text{($T$-APP)} \\ er(x) = x, & er(\lambda x \colon \tau \cdot e) = \lambda x \cdot er(e), & er(e \cdot e') = er(e) \cdot er(e') & \text{(erase)} \\ \text{Implementation sketch:} & & \text{STLC} \\ \text{($define-m$ ($checked-$\lambda \dots$) ($when $T$-ABS$) } er(----)) \\ \text{($define-m$ ($checked-app \dots$) ($when $T$-APP$) } er(-----)) \end{array}
```

**Figure 2.** Simply-typed  $\lambda$ -calculus

in-scope bindings and source location. The macro expander then expands macro invocations in this syntax object according to macro definitions from the program's declared #lang. Macro expansion may reveal additional macro uses or even define new macros, so expansion repeats until no macro uses remain. Compilation terminates with a syntax error if expansion of any macro fails. The output of macro expansion contains only references to Racket's core syntax. This paper shows how to embed type checking within macro expansion.

# 3. A Typed $\lambda$ -calculus Embedded Language

LC from section 2 implements the untyped  $\lambda$ -calculus. This section augments LC with types and type checking by transcribing formal type rules directly into its macro definitions, producing the simply-typed  $\lambda$ -calculus and demonstrating that Racket's macro infrastructure can be reused for type checking. Figure 2 presents standard STLC rules and a skeleton implementation. The macros also erase types in the surface language to accommodate the untyped Racket host.

## 3.1 Typed function application

Figure 3 presents checked-app, a macro that elaborates typed function application nodes into core Racket and also type checks the syntax tree ("v0" marks this initial version). Additional #:with and #:when conditions guard the macro's expansion. A pattern and expression follow a #:with and macro expansion continues only if the result of evaluating the latter produces a syntax object that matches the former. The first #:with uses a compute- $\tau$  function to compute the

<sup>1</sup> Code note: For clarity and conciseness, we stylize code in the paper. Full, runnable code is available at: www.ccs.neu.edu/home/stchang/pop12017/

<sup>&</sup>lt;sup>2</sup>define-m abridges Racket's define-syntax and syntax-parse[10].

<sup>&</sup>lt;sup>3</sup> Appendix A summarizes conventions used in this paper.

```
1 (define-m (checked-app e<sub>fn</sub> e<sub>arg</sub>); v0

2 #:with (\rightarrow \tau_{in} \tau_{out}) (compute-\tau e<sub>fn</sub>)

3 #:with \tau_{arg} (compute-\tau e<sub>arg</sub>)

4 #:when (\tau = \tau_{arg} \tau_{in})

5 #:with \overline{e}_{fn} (erase-\tau e<sub>fn</sub>)

6 #:with \overline{e}_{arg} (erase-\tau e<sub>arg</sub>)

7 (add-\tau (\overline{\#}%app \overline{e}_{fn} \overline{e}_{arg}) \tau_{out}))
```

**Figure 3.** A type checking function application macro

```
1 (define (add-\tau e \tau) (add-stx-prop e 'type \tau))
2 (define (get-\tau e) (get-stx-prop e 'type))
3 (define (compute-\tau e) (get-\tau (local-expand e)))
4 (define (erase-\tau e) (local-expand e))
5 (define (comp+erase-\tau e); get e's type, erase types
6 #:with \overline{\mathbf{e}} (local-expand e) #:with \overline{\mathbf{\tau}} (get-\tau \overline{\mathbf{e}})
7 [\overline{\mathbf{e}} \tau])
8 (define (\tau= \tau1 \tau2) (stx= \tau1 \tau2))
```

Figure 4. Helper functions for type checking

type of function  $e_{fn}$ , which must match pattern  $(\rightarrow \tau_{in} \tau_{out})$ . The second #:with computes the type of argument  $e_{arg}$ , binding it to pattern variable  $\tau_{arg}$ . Unlike the first #:with, the  $\tau_{arg}$  pattern does not constrain the shape of  $e_{arg}$ 's type but the following #:when asserts that  $\tau_{arg}$  and  $\tau_{in}$  satisfy predicate  $\tau$ =. The types in  $e_{fn}$  and  $e_{arg}$  are then erased (lines 5-6) before they are emitted in the macro's output. Finally, add- $\tau$  (line 7) "adds"  $\tau_{out}$  to the macro's syntax object output. In summary, checked-app rewrites a typed function application to an equivalent untyped one, along with its type.

#### 3.2 Communicating macros

The organization of checked-app in figure 3 resembles a combination of its T-APP and erase specification in figure 2. Figure 4 defines some functions needed by checked-app, which together establish a communication protocol between type rule macros. The functions utilize syntax properties, which are arbitrary key-value pairs stored with a syntax object's metadata. For example, checked-app calls  $add-\tau$  to attach type information to its output, which in turn calls add-stx-prop (figure 4, line 1) to associate a type  $\tau$  with key 'type on expression e. If all type rule macros follow this protocol, then to compute an arbitrary expression's type, we simply invoke that expression's macro and retrieve the attached type from its output. In other words, expanding an expression also type checks it.

We can call Racket's macro expander to invoke the desired type checking macro but not in the standard manner. Macro expansion typically rewrites *all* macro invocations in

```
(define-m (checked-app e_{fn} e_{arg}); v1

#:with [\overline{e}_{fn} (\rightarrow \tau_{in} \tau_{out})] (comp+erase-\tau e_{fn})

#:with [\overline{e}_{arg} \tau_{arg}] (comp+erase-\tau e_{arg})

#:when (\tau = \tau_{arg} \tau_{in})

(add-\tau (\overline{\#}_{app} \overline{e}_{fn} \overline{e}_{arg}) \tau_{out}))
```

**Figure 5.** Revise fig 3 to compute and erase types together

a program at once (figure 1) and repeats this process until there are no more macro calls Such breadth-first expansion is incompatible with type checking, however, which proceeds in a depth-first manner—a term is well-typed only if its subterms are well-typed—but the local-expand [17] function controls expansion in the desired way, expanding just one syntax object without considering other parts of the program. Thus compute- $\tau$  expands its argument with local-expand (figure 4, line 3) and then retrieves its type.

The checked-app macro uses  $erase-\tau$  to produce syntax without type annotations. If all type rule macros follow this protocol then *expanding an expression also erases its types*. Separate calls to  $compute-\tau$  and  $erase-\tau$ , however, unnecessarily expands syntax twice. The  $comp+erase-\tau$  function (lines 5-7) eliminates this redundancy and figure 5's revised checked-app uses this function. In general, we carefully avoid extraneous expansions while type checking so as not to change the algorithmic complexity of macro expansion.

Finally, type checking requires a notion of type equality. We cannot compute mere symbolic equality since types are renamable linguistic constructs:

```
(require (rename [\rightarrow a])) (	au= (a s t) (\rightarrow s t)) ;=> true
```

If we represent types with syntax objects, however, *type* equality is syntax equality and we can reuse Racket's knowledge of the program's binding structure (stx= in figure 4 line 8) to compute type equality in a straightforward manner.

```
(define \rightarrow_{\text{intrnl}} (\lambda _ (ERR "no runtime types")))

(define-m (\rightarrow_{\text{tin}} \tau_{\text{out}}) (\rightarrow_{\text{intrnl}} \tau_{\text{in}} \tau_{\text{out}}))

(define-m (checked-\lambda [x : \tau_{\text{in}}] e); v0

#:with [\overline{x} \ \overline{e} \ \tau_{\text{out}}] (comp+erase-\tau/ctx e [x \tau_{\text{in}}])

(add-\tau (\overline{\lambda} (\overline{x}) \overline{e}) (\rightarrow_{\text{tin}} \tau_{\text{out}})))

(define (comp+erase-\tau/ctx e [x \tau])

#:with (\overline{\lambda} (\overline{x}) \overline{e})

(local-expand; y fresh

(\overline{\lambda} (y) (let-macro [x (add-\tau y \tau)] e)))

#:with \tau_{\text{out}} (get-\tau \overline{e})

[\overline{x} \ \overline{e} \ \tau_{\text{out}}])
```

**Figure 6.** Type checking  $\lambda$  and  $\rightarrow$  macros

<sup>&</sup>lt;sup>4</sup> An overline marks type-erased expressions and also core Racket forms.

## 3.3 Type environments and type checking $\lambda$

Figure 6 implements the  $\rightarrow$  type (lines 1-2) as a macro that matches on an input and output type and expands to an application of an internal function that errors at runtime. The checked- $\lambda$  macro requires a type annotation on its parameter (line 4), separated with: This macro resembles checked-app, except a new comp+erase- $\tau$ /ctx function replaces comp+erase- $\tau$ . Since the  $\lambda$  body may reference x, comp+erase- $\tau$ /ctx computes the body's type in a type context containing x and its type, given as the second argument.

So far, checked-app and checked- $\lambda$  correspond to T-APP and T-ABS from figure 2, respectively. To implement T-VAR, i.e., type environments, comp+erase- $\tau$ /ctx defines a local macro with let-macro (figure 6, line 11) and expands an expression e in the scope of this new macro. The local macro is named x and expands to a fresh y that has the desired type  $\tau$  attached (observe the nested gray highlights). As a result, while expanding e, a reference to x (with no type information) becomes a reference to y (with type information). To avoid unbound y errors during expansion, a (Racket)  $\lambda$  wraps the let-macro before expansion. Finally, comp+erase- $\tau$ /ctx returns a tuple of post-expansion y (as  $\overline{x}$ ), the erased  $\overline{e}$ , and its type  $\tau_{out}$ . Effectively, defining a local macro inserts a binding indirection level during macro expansion, enabling the insertion of the desired type information on variable references. Thus we implement T-VAR, reusing the compile-time macro environment as the type environment. This completes our simply-typed language.

#### 3.4 A few practical matters

We have implemented a basic  $\lambda$ -calculus; however, we wish to implement practical languages. This subsection shows how to extend our language with some practical features.

Multiple arguments Figure 7 revises our language to support multiple arguments and useful error messages. An ellipses pattern (...) matches zero-or-more of the preceding element. If that preceding element binds pattern variables, ellipses must follow later references to those variables, e.g., the revised  $\rightarrow$  macro (line 1) matches zero-or-more input arguments  $\tau_{in}$  and ellipses follows  $\tau_{in}$  in its output. The other forms are extended similarly. The checked- $\lambda$  macro (line 13) uses a slightly modified comp+erase- $\tau$ /ctx (not shown) that accepts multi-element contexts. In checked-app (line 5), the "vector"  $\overrightarrow{f}$  notation denotes f mapped over its input list.

Error messages The checked-app in figure 5 reports type errors as syntax errors but a better message should indicate the error's location and the computed and expected types. The checked-app in figure 7 reports such a message using a #:fail-unless condition (lines 6-8) to produce a message from a printf-style string and arguments (this-stx is the current input syntax, analogous to the OO "this"). All our languages strive to report accurate messages in the manner of figure 7, though the paper does not always show this code.

```
(define-m (\rightarrow \tau_{in} \dots \tau_{out}) (\rightarrow_{intrnl} \tau_{in} \dots \tau_{out}))

(define-m (checked-app e_{fn} e_{arg} ...); v2

#:with [\overline{e}_{fn} (\rightarrow \tau_{in} \dots \tau_{out})] (comp+erase-\tau e_{fn})

#:with ([\overline{e}_{arg} \tau_{arg}] \dots) (\overline{comp}+erase-\overline{\tau} (e_{arg} \dots))

#:fail-unless (\overline{\tau} = (\tau_{arg} \dots) (\tau_{in} \dots))

(fmt "~a: Fn args have wrong types: expected: ~a, got: ~a''

(src this-stx) (\tau_{in} \dots) (\tau_{arg} \dots))

(add-\tau (#%app \overline{e}_{fn} \overline{e}_{arg} \dots) \tau_{out}))

(define-m (checked-\lambda ([x:\tau_{in}] ...) e); v1

#:with [\overline{xs} \overline{e} \tau_{out}]

(comp+erase-\tau/ctx \overline{e} ([x \tau_{in}] ...))

(add-\tau (\overline{\lambda} \overline{xs} \overline{e}) (\rightarrow \tau_{in} \dots \tau_{out})))
```

Figure 7. Multi-arity functions and error checking

Figure 8. Checking type well-formedness

Type well-formedness Our language so far checks the types of terms but does not check whether programmer-written types are valid, e.g., one may write  $(\lambda \ ([x : (\rightarrow)]) \ x)$  or  $(\lambda \ ([x : Undef]) \ x)$ . Applying these functions result in type errors but the invalid types should be reported before then. Some type checkers validate types during parsing; this is undesirable for our purposes since it prevents defining types not expressible with a grammar. Instead, we use kinds.

To check kinds, we use the same type checking technique from our term-checking macros. Figure 8 defines a single kind named #%type and all types are tagged with this kind (e.g., line 9). Thus,  $\rightarrow$  and  $\lambda$  may validate their input types with valid- $\tau$ ? (lines 7-8, 12-13). The use of the macro

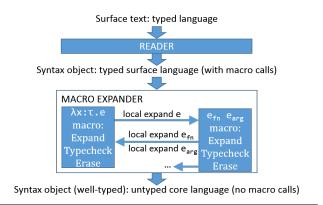

Figure 9. Macro-based typed language implementations

$$\begin{array}{c} e=x\mid\lambda x\colon\tau\cdot e\mid e\:e & \tau=\tau\to\tau & \text{(typed terms, types)}\\ \overline{e}=\overline{x}\mid\lambda\overline{x}\:.\overline{e}\mid\overline{e}\:\overline{e} & \Gamma=x\gg\overline{x}\colon\tau,\dots & \text{(untyped terms, ctx)}\\ \\ \frac{x\gg\overline{x}\colon\tau\in\Gamma}{\Gamma\vdash x\gg\overline{x}\:\colon\tau} & \text{(TE-Var)}\\ \\ \frac{\Gamma,x\gg\overline{x}\colon\tau_1\vdash e\gg\overline{e}\:\colon\tau_2\quad\overline{x}\notin e}{\Gamma\vdash\lambda x\colon\tau_1\:.e\gg\lambda\overline{x}\:.\overline{e}\:\colon\tau_1\to\tau_2} & \text{(TE-Abs)}\\ \\ \frac{\Gamma\vdash e_1\gg\overline{e}_1\:\colon\tau_1\to\tau_2\quad\Gamma\vdash e_2\gg\overline{e}_2\:\colon\tau_1}{\Gamma\vdash e_1\:e_2\gg\overline{e}_1\:\overline{e}_2\:\colon\tau_2} & \text{(TE-App)} \end{array}$$

Figure 10. Interleaved typechecking and erasure rules

expander to validate types also differentiates when a type is undefined, rather than malformed. Ultimately, the previous examples now produce type errors:

```
(\lambda ([x : (\rightarrow)]) x) ; TYERR: \rightarrow requires >= 1 args (\lambda ([x : Undef]) x) ; TYERR: unbound id Undef
```

# 4. A Metalanguage For Typed Languages

### 4.1 Interleaved type checking and rewriting

Section 3's STLC implementation reveals a synergy between macro expansion and type checking in that Racket's macro infrastructure can be reused to also check and erase types during its program traversal. Figure 9 refines figure 1 to incorporate this reuse. This organization further suggests a reformulation of figure 2's rules to combine typechecking and erasure, shown in figure 10. A new  $\Gamma \vdash e \gg \overline{e} : \tau$ rule reads "in context  $\Gamma$ , e erases to  $\overline{e}$  and has type  $\tau$ ", where contexts consist of variable "erasures", e.g., TE-ABS inserts a binding indirection level in the context in order to add type information for variables and checks a  $\lambda$  body in this context. These rules straightforwardly correspond to our macro-based type system implementation in section 3, where  $\Gamma \vdash e \gg \overline{e} : \tau$  is implemented as "in context  $\Gamma$ , e expands to  $\overline{e}$ , with type  $\tau$  attached". As this paper focuses on implementation, we do not formally study these new typing rules, though they do suggest how to further improve our approach to implementing typed embedded languages.

Figure 11. The STLC implemented with TURNSTILE

### **4.2** The TURNSTILE metalanguage

Section 3 demonstrates that a macro system's infrastructure can be reused to implement typechecking. Deploying such an approach, however, requires writing macro-level code to embed type rules into macro definitions despite the resemblance of this code its mathematical specification. This section introduces TURNSTILE, a Racket DSL for creating practical embedded languages that abstracts the macro-level ideas and insights from the previous section into linguistic constructs at the level of types and type systems.

Specifically, TURNSTILE enables writing rules using the syntax from figure 10 but with bidirectional [37] "synthesize" ( $\Rightarrow$ ) and "check" ( $\Leftarrow$ ) arrows replacing the colon, to further clarify inputs and outputs. Figure 11 reimplements STLC with TURNSTILE. TURNSTILE repackages all the infrastructure from section 3 as convenient abstractions, e.g., define-type-constructor (d-t-c) on line 2 and the subsequent define-typerules (d-t) implementing #%app and  $\lambda$ .

TURNSTILE's syntax further demonstrates the connection between specification and implementation enabled by our macro-based approach. Though programmers may now write in a declarative syntax, STLC's implementation has not changed as TURNSTILE's abstractions are mere syntactic sugar for the macros from section 3. For example,  $\Rightarrow$  abbreviates #:with used with comp+erase- $\tau$  and thus figure 11, line 4 exactly corresponds to figure 7, line 4. Similarly, ← abbreviates #:with, #:fail-unless, and  $\tau$ = so figure 11, line 5 corresponds to figure 7, lines 5-8. Finally,  $\Rightarrow$  below the conclusion line corresponds to add- $\tau$  as in figure 7, line 9 (crossing the conclusion line inverts the yellow and gray positions of  $\Rightarrow$ ). In the  $\lambda$  type rule, writing variables and types to the left of  $\vdash$  (figure 11, line 9) computes the operations on the right with these bindings added to the type environment. The  $\lambda$  input pattern (line 8) also utilizes extra annotations asserting that x is an identifier and  $\tau_{in}$  is a valid type.

In general, a d-t resembles the rules in figure 10 except the conclusion is split into its inputs and outputs: the input pattern(s) (and  $\gg$ ) begin a definition and the outputs follow

<sup>&</sup>lt;sup>5</sup> Appendix B compares TURNSTILE syntax and Racket code side-by-side.

the conclusion line such that the definition, and pattern variable scope, reads top-to-bottom. When viewed as type rules, figure 11 appears to be missing the  $\Leftarrow$  version of each rule. While a programmer may write explicit  $\Leftarrow$  rules (explained later), in their absence, TURNSTILE uses a default rule:

```
(define-typerule e \leftarrow \tau \gg [\vdash e \gg \overline{e} \Rightarrow \tau_e]
[\tau_e = \tau]
[\vdash \overline{e}])
```

This implicit type rule again corresponds to figure 7, lines 5-8. The first and last lines again comprise the input and output components, respectively, of the rule's "conclusion", with the type now a part of the input pattern matching.

Though TURNSTILE programmers may implement type rules in a declarative style, such a style is likely insufficient for creating practical languages. Therefore, all the macro features from section 3 are also available to a d-t definition, giving TURNSTILE type rules access to the full power of Racket's macro system. For example, a programmer may add #:fail-unless error messages as in figure 7. Here is a refined #%app that further differentiates arity errors:

### 4.3 Reusing a Type System

TURNSTILE type rules from one language may be reused in the implementation of another. Though STLC implements function application and  $\lambda$ , it defines no base types and thus no well-typed programs. Thus we add integers and addition but instead of revising STLC, we reuse its rules in a new language, analogous to section 2. Specifically, STLC+PRIM in figure 12 uses STLC as a library, importing and re-exporting its type rules with extends. To STLC's definitions, STLC+PRIM adds an Int base type (line 2), a + primop (line 3), and integer literals (lines 4-7). Just as the macro expander inserts #%app before applied functions, it also wraps literals with #%datum, whose behavior is overridden in figure 12 to add types to integers. With STLC+PRIM, we can now write well-typed programs.

# 5. A Series of Core Languages

To confirm that our approach to typed languages handles a variety of type systems, we implemented a series of textbook core languages [36]. This section describes a few examples.

Figure 12. A language extending STLC with integers

# 5.1 Types that bind: existential types

Figure 13 depicts EXIST, a language with existential types; it reuses records and variants from another language. The #:bvs option (line 2) specifies that an  $\exists$  type binds one variable and thus has surface syntax ( $\exists$  (X)  $\tau_{body}$ ).

Figure 4 (line 8) introduced type equality as stuctural equality of syntax objects. Type equality of quantified types, however, should include alpha equivalence. While other systems may convert to alternate representations such as de Bruijn indices [6] to implement this behavior, our use syntax objects for types remains sufficient since it allows reuse of the scoping information already maintained in these objects. Thus the  $\tau$ = used by TURNSTILE looks like:

```
(define [(\tau= (C<sub>1</sub> Xs \tau<sub>3</sub>) (C<sub>2</sub> Ys \tau<sub>4</sub>))

(and (\tau= C<sub>1</sub> C<sub>2</sub>) (\tau= (subst Ys Xs \tau<sub>3</sub>) \tau<sub>4</sub>))]

[else ————]); structural traversal
```

This updated  $\tau$ = specifies multiple input patterns. The first clause matches binding types where equality of such types with the same constructor is equivalent to renaming parameter references to the same name and recursively comparing the resulting body for equality. Otherwise, types are structurally compared. A subst function performs this renaming:

```
(define (subst v x e)
  (if (and (id? e) (binds? x e)) v —— ; else traverse e))
```

Specifically, (subst  $v \times e$ ) replaces occurrences of x in e with v, where binds? determines "occurrence" by examining lexical information in the syntax objects. Thus substitution is a structural traversal and no renaming is necessary.

The pack and open macros use  $\tau$ = and subst: pack assigns a term e an existential type ( $\exists$  (X)  $\tau_{\rm body}$ ), where e has concrete type equal to replacing X in  $\tau_{\rm body}$  with  $\tau_{\rm hide}$ ; dually, open binds x to an existentially-typed epacked's value, type variable X to epacked's hidden type, and then checks an expression e in the context of X and x. To the left of  $\vdash$  (figure 13, line 9) is two environments: a list of type variables and the standard environment for term variables. The ( $\exists$  (Y)  $\tau_{\rm bod}$ ) type of epacked is "opened", so x has type  $\tau_{\rm bod}$  but with occurrences of the existentially-bound Y (not in scope in e) replaced with its "opened" X name. Here is a typical counter example ( $\times$ , rcrd, and prj correspond to records):

```
#lang exist
(define COUNTER
  (pack [Nat (rcrd [new = 1][inc = add1]
```

```

#### 5.2 Subtyping and enhanced modularity

Figure 14 presents STLC+SUB, a language with subtyping that reuses parts of STLC+PRIM from figure 12. It defines new base types and redefines #%datum and + with these types. One might not expect STLC+SUB to reuse type rules that do not consider subtyping. However, TURNSTILE exposes hooks for common type operations and implements type checking in terms of these hooks, enabling better reuse. For example,  $\tau$ = in figure 5, line 4 is actually an overridable "type check relation" (initially set to  $\tau$ =). These hooks are implemented with Racket *parameters* [20], which specify dynamic extent; here they behave like module-level variables. Thus STLC+SUB defines a new  $\tau$ <: predicate and installs it as the  $\tau$  type check relation (we oval-box parameter names), enabling reuse of #%app and  $\lambda$  from section 3.

### 5.3 Defining types and kinds

Our implementations macro-expand a term to type check and erase its types. We check kinds in the same way: expanding a type kind checks and erases kinds. The kind erasing may cause problems, however, since a type judgement may use both types and kinds. Nevertheless, TURNSTILE can define a kind system like in  $F_{\omega}$ . To address the problem, figure 15 reformulates some  $F_{\omega}$  rules with our  $\gg$  relation. Specifically, T-TABS and K-ALL erase a  $\forall$ 's kind annotation, but "save" it with  $\star$ , now a kind constructor, in the same manner that  $\rightarrow$  "saves" a  $\lambda$ 's type annotations. T-TAPP then checks that its argument type has a kind matching the saved annotation.

Figure 16 implements FOMEGA utilizing figure 15's insights: it introduces a "kind" category of syntax, defines  $\Rightarrow$  and  $\star$  kinds, and directs the  $\forall$  type to construct its kind with a  $\star$  "arrow". Lines 8-9 connect "kinds" and "types" where line 8 enables reuse of previously-defined types, and line 9 redefines "well-formed" types. Finally, the  $\Lambda$  rule type checks its

```

```

**Figure 15.** Some  $F_{\omega}$  rules using figure 10's  $\gg$  relation

body in its type variable's context, and the inst rule instantiates an expression e at type  $\tau$  by computing e's  $\forall$  type and that type's kind ( $\star\kappa$ ), and checking that  $\tau$  has kind  $\kappa$ .

#### 5.4 Reusing languages

Table 1 summarizes extensions and reuse in fourteen core language implementations. A row and color represents a language and features are in columns. Parameter names like  $\tau<:$  are ovalboxed. A diamond marks a feature's first implementation and subsequent appearances of the feature's color in the column indicates reuse. Thus single-color columns and multi-color rows indicate *abundant* reuse. For example, all languages share the same  $\lambda$ ; also, languages with basic types share a  $\tau$ = while those with binding types use an extended version. A  $\oplus$  marks feature extension (a dotted line connects non-adjacent-row extensions) For example, "sub-

Figure 16. A language with higher-order polymorphism

typing" extends #%datum from "stlc+prim"; also,  $F_{<:}$  extends and combines subtyping from one language and  $\forall$  from system F to implement bounded polymorphism.

Table 2 summarizes implementation sizes from table 1. Each column represents a different implementation of the same language: the first uses TURNSTILE; the second uses TURNSTILE but does not import other implementations; and the third uses plain Racket. Though the last two columns are estimations (we did not implement every permutation of every language) they still indicate a degree of reuse. Roughly, the second and first column difference represents the degree to which type rules are reused across many languages, analogous to single-color columns in table 1. The third and first column difference indicates the degree to which TURNSTILE captures common patterns used to implement type checkers. The similarity of this latter difference for all languages demonstrates the usefulness of TURNSTILE's abstractions.

### 5.5 More than types: a type-and-effect system

Table 1's languages mostly use a typical  $\Gamma \vdash e : \tau$  relation though TURNSTILE is not limited to this relation. Rather, programmers may specify propagation of any number of arbitrary properties. For example, figure 17 presents EFFECT, a language with a basic type and effect system [33]. The language adds Void and Ref types, and ref, deref, and := type rules for allocation of, dereference of, and assignment to reference cells, respectively (box is Racket's ref cells). In addition to types, the language tracks source locations  $(\pi)$  of ref allocations (line 9). The ref rule exhibits new syntax: instead of a type to the right of  $\Rightarrow$ , a programmer may write multiple  $\Rightarrow$  arrows matching multiple properties. Thus ref specifies that expansion of e (line 6) computes both a type

```

**Figure 17.** A basic side effect analysis.

(keyed on :) and a set of locations  $\pi$  (keyed on : $_{\nu}$ ). The key symbols match the user-specified symbols below the conclusion line. The := rule uses both  $\Leftarrow$  (for the type) and  $\Rightarrow$  (for the locations) simultaneously (line 16).

EFFECT contrasts with table 1's languages in that it cannot reuse #%app and  $\lambda$  due to its incompatible type relation. (It does reuse some types and type operations.) The new #%app and  $\lambda$  rules show that both terms and types carry the : $_{\nu}$  property. Specifically,  $\lambda$  propagates : $_{\nu}$  to function types (line 29), expressed with a  $nested \Rightarrow$  (geneneralizing the double- $\Rightarrow$  syntax for kinds from figure 16), because evaluating a  $\lambda$  does not trigger allocations in its body. Applying a function does evaluate the body, so #%app transfers locations from the function type (line 20) to the application term (line 25).

Table 2. Line count comparisons of table 1's languages

# 6. A Full-sized Language

To show that TURNSTILE scales to real-world type systems, we created MLISH, an ML-like language with local type inference, recursive user-defined algebraic data types, pattern matching, and Haskell-style type classes [45], along with "batteries included" features like efficient data structures, mutable state, generic sequence comprehensions, I/O, and concurrency primitives. MLISH also demonstrates how TURNSTILE easily incorporates type-system-directed program transformations. This section explains a few features.

**Local type inference** MLISH aims to follow Pierce and Turner's empirical inference guidelines [37]. Specifically, programmers need not write most annotations and instantiations except top-level function signatures, which are useful as documentation, and some  $\lambda$  annotations, which are rare.

Figure 18 sketches basic type inference in  $\lambda$  and #%app. Multiple clauses comprise  $\lambda$ , whose input patterns are checked in order. The first clause matches unannotated  $\lambda$ s whose context determines its type, indicated with  $\Leftarrow$  (line 5). The second matches annotated  $\lambda$ s with implicitly bound type variables, computes these variables, and then recursively invokes the  $\lambda$  rule (indicated with  $\succ$ ) with explicit type variables. In this manner, a surface language with implicit type variables rewrites to one with explicit binders, reusing the macro system for the type-system-directed rewrite. Finally, the third clause matches  $\lambda$ s with explicit type variable binders; it resembles  $\lambda$  from figure 11. An MLISH define for top-level functions uses  $\lambda$ , splitting a definition into a runtime component and a macro that adds type information:

To implement a ← type rule, e.g., figure 18 lines 5-8, MLISH propagates "expected type" information from an ex-

Figure 19. Defining types and pattern matching in MLISH

cursively invokes #%app with explicit instantiation types. In this manner, a surface language with inferred instantiation rewrites to one with explicit instantiation. The second #%app clause resembles the first except it does not use the expected type. The third instantiates the polymorphic function type (line 39) and then checks function arguments as in figure 11. Algebraic datatypes Figure 19's define-type macro enables sum-of-products algebraic datatype definitions in MLISH; it expands to a series of definitions (gray box): a type constructor (lines 3-5), where the #:extra argument communicates information about the type to other type rules, e.g., to check match clause completeness; Racket structs (line 6) implementing runtime constructors; and type rules (lines 7-11) that leverage #%app to instantiate polymorphic constructors. Pattern matching In figure 19's match, (one or more) clauses follow e<sub>m</sub>, matching its possible variants. The rule uses "extra" information in the type representation to check exhaustiveness of clauses (lines 14-17). Otherwise match expands to a conditional that extracts components of em using appro-

priate predicates and accessors (that are also derived from

**Figure 20.** Type classes in MLISH

Type classes require intertwined typechecking and program rewriting. Figure 20 sketches an implementation, demonstrating how TURNSTILE's combined rules naturally accommodate such a system. MLISH supports type classes with basic features such as subclassing (unsupported features include multi-parameter type classes and overlapping instances). For simplicity, this paper explains single-operation type classes, though MLISH supports the standard dictionary. The define-tc form shows that two definitions implement a type class: a macro for the type class itself (line 2) that expands to its generic operation and type, and a type rule for that operation (lines 3-7) that looks up a concrete operation (line 5) based on the generic name and the concrete types of its usage. MLISH type classes reuse the compiletime macro environment for lookups, where a concrete operation's name, installed by define-instance (lines 8-14), is a mangling of the generic name and specific concrete types.

Consequently, functions utilizing generic operations (not shown) have a typeclass component in their type (the => constructor on line 18) and these functions implicitly have an extra concrete operation argument. The #%app rule implicitly inserts this argument by: extracting the generic operation of the type class (line 21); looking up the concrete operation

Table 3. Testing TURNSTILE-created languages

based on instantiation types for the function (lines 22-23); and adding this operation to the application (line 25).

# 7. Creating a Test Suite

Sections 5 and 6 show that our approach accommodates a variety of typed languages. This section explains how we validate these languages with a large test suite that includes a variety of real-world programs [1, 2, 31, 34]. To implement this test suite, we created a type system unit-testing framework that considers both typechecking successes and failures, including error messages. It also enables writing tests in a language's surface syntax rather than an internal AST structure. The following defines a function f, and tests the type of f and both a successful and failing application of f:

```
#lang mlish (require typechecker-tester) (define (f [x : Int] \rightarrow Int) x) (check-type f : (\rightarrow Int Int)) (check-type (f 1) : Int => 1) (typecheck-fail (f 1 2) #:msg "Wrong number of args")
```

Table 3 summarizes our test suite, which includes both "coverage" tests checking general functionality and corner cases, and real-world examples. For the latter, Real World OCaml [31] supplied functional tests while the Benchmarks Game [1] consisted of more imperative tests. Okasaki's data structures tested the limits of our type system. For example, in discussing polymorphic recursion (ch. 10), he writes:

"We will often present code as if SML supports [polymor. recursion]. This code will not be executable but will be easier to read."

We were able to add polymorphic recursion to MLISH, by leveraging recursive definition forms in the host, and to implement the data structures in question, demonstrating both the ability to implement tricky type system features with TURNSTILE, and the ease with which one can do so.

#### 8. Related Work

Researchers have developed many frameworks for writing *type system extensions* [3, 5, 12, 14, 30, 35, 47]. These systems, however, are designed to extend their host languages and typically defer to the host's type system to compute type checking. As such, any new rules must be expressible with the underlying type system. Contrastly, our approach does not require commitment to a particular type system but a programmer may have to implement more type rules. Our approach attempts to simplify the latter as much as possible. *Typed Racket* [40] pioneered the idea of implementing a typed language with syntax extensions of an untyped language. While our paper shares this approach at a high-level,

the novelty of our work stems not from the use of macros to implement typed languages but the manner in which we do so. Specifically, Typed Racket builds a type system from scratch and calls out to it after macro expansion. Since it does not reuse Racket's implementation for typechecking, Typed Racket is considered a "sister" language [41] to Racket rather than a language embedded in Racket. Further, Typed Racket's typechecker implementation itself is not easily reused to help implement other typed languages, as users attest [23, 27]. We conjecture that reimplementing Typed Racket in our framework would improve its reusability. The availability of type information during macro expansion may also enable new type features such as generic operations, a feature that Typed Racket has struggled to implement.

The *TinkerType* [29] system also separates type rules and type operations into reusable components, which resembles our modularization of type systems into macro components. Though the framework stitches together raw string components, and is designed for modeling and typesetting typed language calculi rather than creating practical languages, our approach may benefit from some of the consistency checks that TinkerType performs when combining components. We plan to explore this in future work; for now, the time-honored task of proving type soundness remains for human experts.

### 9. Conclusions and Future Work

We present a novel use of macros to create practical, performant typed embedded languages. Our approach is not constrained to a particular type system, yet programmers do not have to implement a system from scratch because they can reuse the infrastructure of a macro system. To this end we introduce TURNSTILE, a metalanguage that enables creating typed languages by writing combined type and rewriting rules in an intuitive mathematical syntax. We conjecture that many typed language implementers will benefit from our approach, as non-language experts may reduce the burden of language creation, while language researchers may rapidly iterate and experiment with new type features and combinations of features without implementing entire languages.

As next steps, we plan to further validate our approach with the implementation of more languages, and to extend our approach by exploring its application to more complex static analyses. In addition, while this paper presents synergies between type checking and one particular Lisp-style macro system we plan to explore whether the same approach to implementing typed embedded languages is compatible with other syntax extension systems. Finally, we plan to investigate whether the connections between type checking and macro processing that we have described might inform the *future* design of both type systems and macro systems. The fact that many type systems already intertwine type checking and program rewrites [37, 38, 45] suggests that perhaps they should be computed together *by default*. We plan to explore the ramifications of such integration.

# A. Syntax Conventions in the Paper

This appendix summarizes terminology and syntax conventions from paper. This paper utilizes pseudocode whenever it aids readability.

- syntax object: An s-expression of symbols, but infused with context information. This is Racket's data representation of programs, replacing the traditional AST.
- [square brackets]: Square brackets in Racket are semantically equivalent to regular parentheses and are used for readability purposes, typically to denote binding pairs or language forms with multiple clauses.
- a syntax pattern: Syntax patterns deconstruct syntax objects and bind pattern variables. This paper highlights them in yellow. Pattern variables may additionally be tagged with a superscript "syntax class" [10], e.g., type, which specifies additional constraints that must be satisfied in order for the matching to succeed.

- a syntax template: Dual to syntax patterns, syntax templates construct syntax objects, possibly referencing pattern variables. This paper highlights them in gray. Racket code more typically uses the #' constructor.
- syntactic literals: Bolded, Roman-font identifiers in syntax patterns represent literal symbols that must be matched exactly (as opposed to pattern variables). Examples include the colon to separate a function's parameters and types:  $(\lambda \ ([x : \tau]) \ x)$  and the with in (match e with ———).
- $\overline{e}$ : A version of typed-term e where types are erased. We also use the overline to disambiguate Racket's forms (e.g.,  $\overline{\lambda}$ ) from the typechecked version of the form we wish to define in a typed surface language (e.g.,  $\lambda$ ). Typically, the overline is used in the output syntax object of macro definitions.
- ; a comment: Comments in Racket begin with ";" and extend to the end of the line. This paper uses a gray Roman font face to distinguish comments.
- $\overrightarrow{\tau}$ =: The over-arrow notation represents a function lifted to consume compound, e.g. list, inputs. For example ( $\overrightarrow{\tau}$ =  $\tau s_1 \ \tau s_2$ ) is equivalent to repeatedly applying  $\tau$ = to each pair of types in  $\tau s_1$  and  $\tau s_2$ .
- MODULENAME: Module names are boxed, use the small-caps style, and are typically located in a figure's upperright corner. Module names are also language names, e.g., STLC, and typically (but not always) correspond to file names.
- param: Overridable hooks in TURNSTILE. Used to implement type operations, e.g.,  $\tau$ =, in an extensible manner.
- ————: This long dash indicates elided code. We also sometimes use a four-dot ellipses for this purpose (because the three-dot ellipses is a valid syntax pattern).

# B. TURNSTILE vs Racket syntax

This appendix gives an idea of how TURNSTILE's syntax matches up with equivalent Racket macro code.

# Premises:

TURNSTILE	Racket					
$\vdash$ e $\gg \overline{e} \Rightarrow \tau$	#:with $\overline{[e \ \tau]}$ (comp+erase- $\tau$ e)					
$\vdash$ e $\gg$ $\frac{e}{e}$ $\leftarrow$ $\tau_{\text{expected}}$	#:with $\overline{[\mathbf{e} \ \tau]}$ (comp+erase- $ au$ (add-expected- $ au$ $\mathbf{e}$ $ au_{\mathtt{expected}}$ ))					
	#:fail-unless ( $\tau$ $\tau$ $\tau$ $\tau$					
	$\overline{ ext{(typecheck-fail-msg}} \;  au_{ ext{expected}} \;  au \;  ext{e})$					
$[x \gg \overline{x} : \tau_x] \vdash e \gg \overline{e} \Rightarrow \tau$	#:with $\overline{(\overline{x})} \overline{e} \tau$ (comp+erase- $\tau$ /ctx e ([x $\tau_x$ ]))
